PSYCHOSOCIAL SCARS
OF CONFLICT ON CHILDREN

Exposure to bomb blasts, can result in a wide spectrum of psychological and cognitive impairments. Bomb blasts have the capacity to elicit profound psychological distress in exposed populations, and a source of significant physical and psychological injury to children. It potentially manifests in physical and psychological symptoms such as tremors, emotional detachment and numbness that qualify as diagnosable syndromes, indicative of further underlying, concomitant psychosocial issues. The physical ramifications of bomb explosions, such as burning, fractures, and concussions, present an immediate concern. In the long-term aftermath of blast-related trauma, children may find themselves subject to intrusive memories, nightmares, flashbacks of the traumatic experience, and numbing of affect. These psychological reactions are grounded in the initial shock wave stimulus and its impact on somatic functioning.
